## 1986: The Hydrographic Data Problem

The table below gives the depth $Z$ of water in feet for surface points with rectangular coordinates $X, Y$ in yards. The depth measurements were taken at low tide. Your ship has a draft of five feet. What region should you avoid within the rectangle $(75,200) \times(-50,150)$ ?

| $X$ | $Y$ | $Z$ |
| ---: | ---: | ---: |
| 129.0 | 7.5 | 4 |
| 140.0 | 141.5 | 8 |
| 108.5 | 28.0 | 6 |
| 88.0 | 147.0 | 8 |
| 185.5 | 22.5 | 6 |
| 195.0 | 137.5 | 8 |
| 105.5 | 85.5 | 8 |
| 157.5 | -6.5 | 9 |
| 107.5 | -81.0 | 9 |
| 77.0 | 3.0 | 8 |
| 162.0 | -66.5 | 9 |
| 162.0 | 84.0 | 4 |
| 117.5 | -38.5 | 9 |

## Comments by the Contest Director

The problem was contributed by Richard Franke (Dept. of Mathematics, Naval Postgraduate School, Monterey, CA). His paper [1982] compares 34 approaches to this problem.

Two points on the suggested outline for papers received scant attention: testing and (especially) stability. In particular, none of the papers questioned how the depth data-all depths were given in exact numbers of feet-were arrived at: rounding down? truncation? rounding up?

Although the concept of stability (conditioning, robustness, sensitivity, well-posed, etc.) was introduced by the great Jacques Hadamard in 1923, it seems to have difficulty establishing itself in the undergraduate mathematics curriculum.
